# Entertaining LLV theories of gravity

- ▶ quantitatively parametrize deviations from local Lorentz invariance in the gravitational sector,
- ▶ possibility to construct renormalizable QFT of gravity (e.g. Hořava gravity).

# Theories with a preferred foliation

Characteristics of theories (e.g. Hořava gravity) with a *preferred foliation*:

- ▶ solutions admit a *special* foliation  $\Sigma$  (e.g. a scalar field  $T$  has timelike gradient everywhere)

$$u_a \propto -\nabla_a T, \quad g^{ab} u_a u_b = -1.$$

# Theories with a preferred foliation

Characteristics of theories (e.g. Hořava gravity) with a *preferred foliation*:

- ▶ equations of motion 2<sup>nd</sup> order in 'time' *only* w.r.t  $\Sigma$

- ▶ modes have *higher order dispersion relations* w.r.t  $\Sigma$

$$\omega^2 \propto k^6, \quad k \rightarrow \infty.$$

# Theories with a preferred foliation

Characteristics of theories (e.g. Hořava gravity) with a *preferred foliation*:

▶ even at the lowest order (IR), there is an *elliptic* equation which is not preserved under time evolution (i.e.  $\neq$  constraint) – *instantaneous mode*.

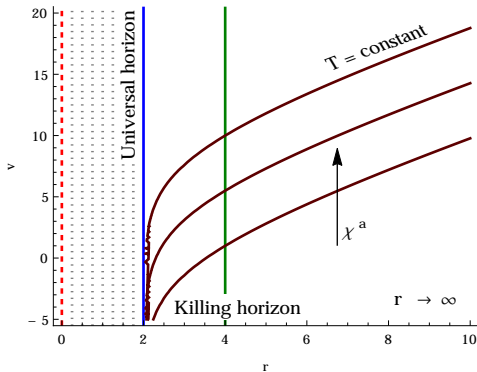

\* \* \* \*

Theories with special foliations but *without* the above properties *do not admit a preferred foliation* – e.g. hypersurface orthogonal Einstein-æther theory.

# Causal structure of LLV spacetimes: why?

- ▶ ensure no conflict with the basic principles of causality;
- ▶ existence of 'out of the lightcone' propagations and 'instantaneous mode' *consistent* with the problem of *well-posed causal development*?
- ▶ can *black holes* exist?

# The universal horizon: lots of symmetries

Eling, Jacobson 2006; Barausse, Jacobson, Sotiriou 2011; Blas, Sibiryakov 2011; Barausse, Sotiriou 2013; Sotiriou, Vega, Vernieri 2014; Berglund, JB, Mattingly 2012; JB, Mattingly 2014.

# Preferred foliation $\equiv$ preferred simultaneity

- ▶ spacetime with a preferred foliation =  $(\mathcal{M}, \Sigma, g_{ab})$

- ▶ preferred foliation is *ordered*: (i)  $p \leftrightarrow \Sigma_p$ , (ii)  $p \neq q$  have *unique* causal relationship.

# Past and future

# Asymptotic boundary: $\mathcal{I}$

# 'Outside region': $\langle\langle \mathcal{M} \rangle\rangle$

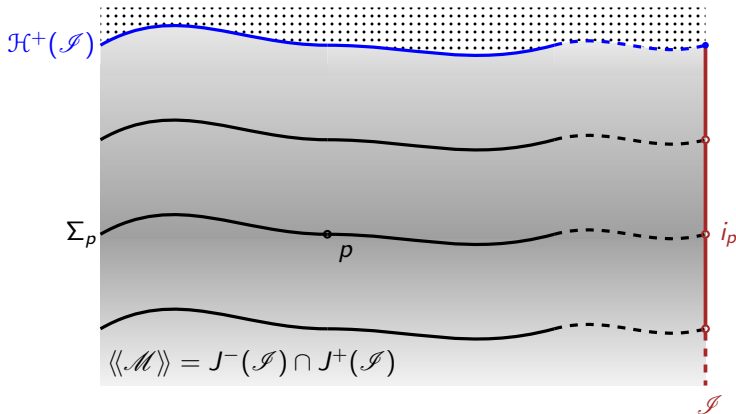

$$\langle\langle \mathcal{M} \rangle\rangle = J^-(\mathcal{I}) \cap J^+(\mathcal{I})$$

# Universal horizon as an event horizon

$$\mathcal{H}^+(\mathcal{I}) = \partial J^+(\mathcal{I})$$

# Universal horizon as a Cauchy horizon

$$\mathcal{H}^+(\mathcal{I}) = \text{Cauchy horizon}(\Sigma_p, \mathcal{I})$$

# Universal horizon: local characterization

$$\mathcal{H}^+(\mathcal{I}) \Leftrightarrow u_a \chi^a = 0$$

## To summarize . . .

- ▶ spacetimes with a *preferred foliation* has a *consistent causal structure*,
- ▶ black holes can exist even though Lorentz invariance is not respected; *event horizon*  $\equiv$  *universal horizon*,
- ▶ *universal horizon*  $\equiv$  *Cauchy horizon* for the 'outside region',
- ▶ in stationary spacetimes with Killing vector  $\chi^a$ , *local characterization* of universal horizon:  $u_a \chi^a = 0$ .
